

2024 4-1 Information Security Team Project

Final

20102104 Kim Sua

20102117 Lee Jeonghyeon

Contents

- **Proposal**
- **Implementation**
 - Card Brand Check
 - Expiry Date
 - Card Validity
- **Performance**
- **Program Execution**

Plan

1. Verify Card Types (Brand)
2. Check the validity period
3. Verify card number

Step 1

Verify Card Types

- The **first digit** of the card number determines the **card types**
 - Starting with 4 : VISA
 - Starting with 5 : Mastercard
 - Starting with 9 : Domestic
- Using comparative operations of homomorphic encryption to distinguish whether the inputted card is a Mastercard, Visa, or Domestic card.

Step 2 **Verify Card Valid Period**

- Verification of the validity period inputted on the card by comparing it with the current date to ensure its validity.

VISA

Step 3

Verify Card Number Validity

- Verify the Card number validity using the algorithm
- Multiply each digit in the odd positions of the card number by 2. If the resulting number is a two-digit number, add the digits together.
- Sum up all the digits in the even positions.
- Add the sums from steps 1 and 2 together.
- Add a specific number to the result from step 3 and adjust the 16th digit of the card number to ensure it is divisible by 10.

VISA

Implementation - Overview

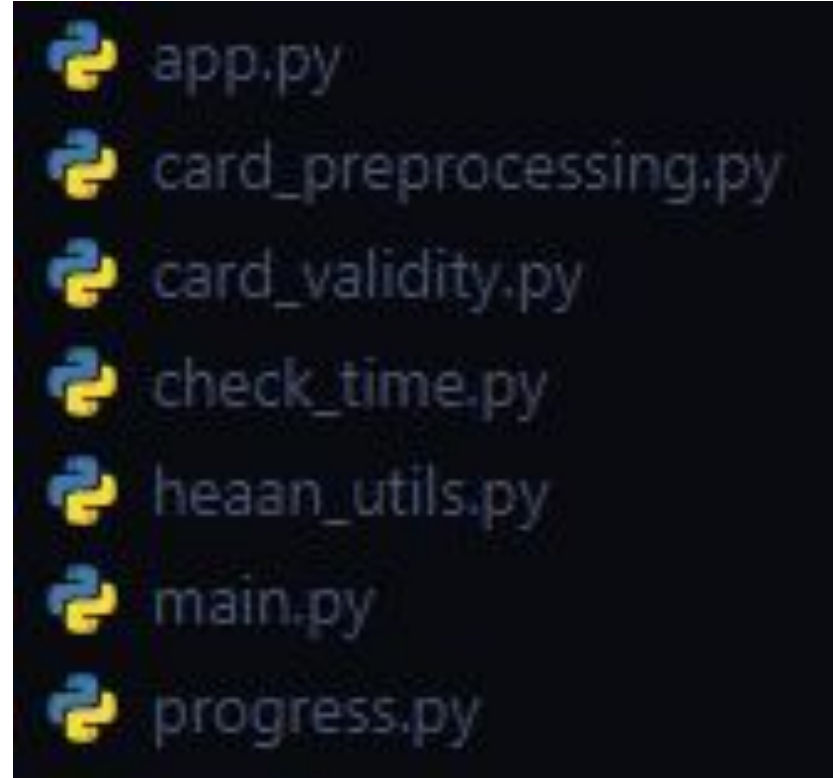

This web application architecture leverages the strengths of HTML for building user interfaces, Flask for handling HTTP requests and server-side routing, and Python for implementing business logic and processing data.

Implementation - Detailed Design

Application Structure

- **app.py:**
The main entry point of the Flask application. Handles routing and starts the server.
- **main.py:**
Handles the input from the HTML form and orchestrates the processing workflow.
- **card_preprocessing.py:**
Contains functions to preprocess the card data.
- **card_validity.py:**
Contains functions to validate the card data.
- **heaan_utils.py:**
Utilizes the Pi-heaan library for secure computations.

Implementation - Detailed Design

app.py

Set up the Flask application, define routes, and render the initial HTML page.

```
Cardify > app.py > validate
1 from flask import Flask, render_template, jsonify, request, redirect, url_for
2 import subprocess
3 import json
4
5 app = Flask(__name__)
6
7 # 전역 변수를 초기화합니다.
8 card_info = {}
9 validation_result = None
10
11 @app.route('/')
12 def index():
13     return render_template("index.html")
14
15 @app.route('/validate', methods=['POST'])
16 def validate():
17     global card_info, validation_result
18     card_info = {
19         "card_number_1": request.form["card_number_1"],
20         "card_number_2": request.form["card_number_2"],
21         "card_number_3": request.form["card_number_3"],
22         "card_number_4": request.form["card_number_4"],
23         "expiry_month": request.form["expiry_month"],
24         "expiry_year": request.form["expiry_year"]
25     }
26     print("카드 정보를 성공적으로 받았습니다.")
27
28     # card_info를 JSON 문자열로 변환합니다.
29     card_info_json = json.dumps(card_info)
30
31     # subprocess를 사용하여 main.py를 실행하고 결과 값을 받습니다.
32     result = subprocess.check_output(["python", "main.py", card_info_json])
33
34     # 결과 값을 validation_result에 저장합니다.
35     validation_result = json.loads(result.decode("utf-8").strip())
36
37     print("validation result: ", validation_result)
```

Implementation - Detailed Design

app.py

- Form Handling:
The /validate route collects card information from the submitted form, processes it using a separate script (main.py), and updates the global variable validation_result with the processed data.
- Subprocess Usage:
The subprocess.check_output function is used to run main.py with the card information passed as a JSON string. The output from main.py is captured and decoded into a JSON object.
- Template Rendering:
The render_template function is used to render HTML templates (index.html and result.html). The result.html template is dynamically updated with the validation result.
- Global Variables:
The use of global variables (card_info and validation_result) allows the application to store and access data across different routes.

Implementation - Detailed Design

templates/index.html & result.html

Provide the user interface

- Index.html : input card information
- result.html : show the results

```

1 <?php

```

Implementation - Detailed Design

main.py

Receive input from the form, invoke preprocessing and validation functions, and return the result.

```
import sys
import json
from heaan_utils import Heaan
from card_preprocessing import preprocess_card_number, preprocess_expiry_date, triple_preprocess_card_number, preprocess_expiry_month
from card_validity import validate_card_num, check_card_brand_method1, check_card_brand_method2, check_card_brand_method3, check_expiry_date

def main(card_info):
    # 카드 번호 전처리
    card_num_txt = preprocess_card_number(card_info)

    # Triple Card num preprocessing
    triple_card_num_txt = triple_preprocess_card_number(card_info)

    # 유효기간 전처리
    valid_thru_txt = preprocess_expiry_date(card_info)

    # Check the Month: JAN ~ DEC
    valid_month = preprocess_expiry_month(card_info)

    card_result = {}

    # Store the results in the dictionary
    card_result['card_validity'] = validate_card_num(card_num_txt)
    card_result['card_brand'] = check_card_brand_method3(triple_card_num_txt)
    card_result['expiry_date_validity'] = check_expiry_date(valid_thru_txt, valid_month)

    return card_result

if __name__ == '__main__':
    # 명령줄 인수로 전달된 JSON 문자열을 파싱합니다.
    card_info = json.loads(sys.argv[1])
    result = main(card_info)
    print(json.dumps(result))
```

Implementation - Detailed Design

main.py

- **Functionality:**
The main function orchestrates the entire workflow: preprocessing card information, validating it, and aggregating results into a dictionary.
- **Preprocessing:**
 - The card number is preprocessed and encrypted using `preprocess_card_number`.
 - The card number is tripled, preprocessed, and encrypted using `triple_preprocess_card_number`.
 - The expiration date is preprocessed and encrypted using `preprocess_expiry_date`.
 - The expiration month is preprocessed, encrypted, and scaled using `preprocess_expiry_month`.
- **Validation:**
 - The card number's validity is checked using `validate_card_num`.
 - The card brand is checked using `check_card_brand_method3`.
 - The expiration date validity is checked using `check_expiry_date`.
- **Command-Line Interface:**
 - The script is designed to be executed from the command line, with card information passed as a JSON string argument.
 - The script outputs the validation results in JSON format, suitable for further processing or display.

Implementation - Detailed Design

card_preprocessing.py

Preprocess the card number and expiration date.

```
from heaan_utils import Heaan

# Heaan 클래스의 인스턴스 생성
heaan_instance = Heaan()

# Heaan 클래스의 메서드 호출
heaan_instance.initialize()

def preprocess_card_number(card_info):
    card_number = [int(num) for i in range(1, 5) for num in card_info[f'card_number_{i}']]

    card_num = heaan_instance.feat_msg_generate(card_number)

    card_num_ctxt = heaan_instance.encrypt(card_num)

    return card_num_ctxt

def preprocess_expiry_date(card_info):
    expiry_month = int(card_info['expiry_month'])
    expiry_year = int(card_info['expiry_year'])
    valid_thru = [expiry_year * 100 + expiry_month]

    valid_thru = heaan_instance.feat_msg_generate(valid_thru)

    valid_thru_ctxt = heaan_instance.encrypt(valid_thru)

    return valid_thru_ctxt

def preprocess_expiry_month(card_info):
    expiry_month = int(card_info['expiry_month'])

    month_msg = heaan_instance.feat_msg_generate([expiry_month])

    month_ctxt = heaan_instance.encrypt(month_msg)

    month_ctxt = heaan_instance.multiply(month_ctxt, 0.01)
```

Implementation - Detailed Design

card_preprocessing.py

- **Initialization:**

An instance of the Heaan class is created and initialized to prepare the HEAAN library for processing and encryption tasks.

- **Function Descriptions:**

Each function processes specific parts of the card information and encrypts them using HEAAN's methods. These functions are designed to handle the card number and expiration date securely.

- **Feature Message Generation and Encryption:**

- The feat_msg_generate method of the Heaan instance is used to convert data into a format suitable for encryption.
- The encrypt method encrypts the processed data.
- The multiply method scales the encrypted data in the preprocess_expiry_month function.

Implementation - Detailed Design

card_validity.py

Validate the preprocessed card data.

```
Cardify > card_validity.py > check_card_brand_method2
1 from heaan_utils import Heaan
2 from card_preprocessing import preprocess_card_number, preprocess_expiry_date, triple_preprocess_card_number, preprocess_expiry_month
3 from datetime import datetime
4
5 import logging
6
7 # 로깅 설정
8 logging.basicConfig(level=logging.DEBUG) # DEBUG 레벨 이상의 로그를 출력
9
10
11 he = Heaan()
12
13 def validate_card_num(ctxt):
14     # Double the value of digits at odd positions
15     double_odd_ctxt = he.multiply(ctxt, 2)
16
17     # If doubling results in a two-digit number, sum the digits
18     cnt, remain = he.division(double_odd_ctxt, 10)
19
20     addition_remain_cnt = he.addition(cnt, remain)
21     addition_remain_cnt_msg = he.decrypt(addition_remain_cnt)
22
23     total = he.feat_msg.generate([0])
24     total_ctxt = he.encrypt(total)
25
26     for i in range(16):
27         if i % 2 == 0:
28             if round(addition_remain_cnt_msg[i].real, 2) > 0:
29                 total_ctxt = he.addition(addition_remain_cnt, total_ctxt)
30             else:
31                 total_ctxt = he.addition(double_odd_ctxt, total_ctxt)
32         else:
33             total_ctxt = he.addition(total_ctxt, ctxt)
34
35     addition_remain_cnt = he.left_rotate(addition_remain_cnt, 1)
36     double_odd_ctxt = he.left_rotate(double_odd_ctxt, 1)
37     ctxt = he.left_rotate(ctxt, 1)
```

Implementation - Detailed Design

card_validity.py

- `validate_card_num(ctxt):`
 - This function validates a card number using the Luhn algorithm.
 - It doubles the value of digits at odd positions and sums the digits if doubling results in a two-digit number.
 - The total sum of all digits is then checked to see if it is divisible by 10 to determine the validity of the card number.
- `check_card_brand_method1(ctxt):`
 - This function checks the brand of a card by comparing the first digit of the card number to known prefixes (4 for Visa, 5 for MasterCard, 9 for Domestic cards).
- `check_card_brand_method2(ctxt):`
 - This function checks the brand of a card using a different method by rotating the prefix and comparing it to the card number.
- `check_card_brand_method3(ctxt):`
 - This function checks the brand of a card by subtracting the prefix from the card number and checking for equality to zero.
- `check_expiry_date(ctxt, month_ctxt):`
 - This function checks if the card's expiry date is valid by comparing it to the current date and ensuring the month is within the range of 1 to 12.

Implementation - Detailed Design

heaan_utils.py

Utilize PI-HEAAN library functions for secure computations.

```
Cardify > heaan_utils.py > Heaan > division
1 import os
2 import re
3 from datetime import datetime
4 import piheaan as heaan
5 from piheaan.math import sort
6 from piheaan.math import approx
7 import math
8
9 class Heaan:
10     def __init__(self, key_file_path="./keys", log_slots=15):
11         self.context = heaan.make_context(heaan.ParameterPreset.FGb)
12         heaan.make_bootstrappable(self.context)
13         self.key_file_path = key_file_path

```

Implementation - Detailed Design

heaan_utils.py

- Homomorphic Operations:
 - `check_card_brand(self, card_num_ctxt)`: Checks the brand of a credit card based on the encrypted card number.
 - `feat_msg_generate(self, feat)`: Generates a message from a feature array.
 - `encrypt(self, plaintext)`: Encrypts a plaintext list.
 - `decrypt(self, ciphertext)`: Decrypts a ciphertext.
 - `division(self, divided, divider)`: Divides one encrypted number by another.
 - `multiply(self, ctxt, factor)`: Multiplies an encrypted number by a constant factor.
 - `subtract(self, ctxt1, ctxt2)`: Subtracts one encrypted number from another.
 - `addition(self, ctxt1, ctxt2)`: Adds two encrypted numbers.
 - `equal_zero(self, ctxt)`: Checks if an encrypted number is zero.
 - `left_rotate(self, ctxt, rotation_amount)`: Rotates an encrypted number to the left.
 - `right_rotate(self, ctxt, rotation_amount)`: Rotates an encrypted number to the right.
 - `comparing(self, ctxt1, ctxt2)`: Compares two encrypted numbers.

Implementation - Card Types

Method 1

- Encrypt predefined messages representing Visa, MasterCard, and Domestic brands.
- Subtract each encrypted message from the provided encrypted card number context.
- Decrypt the results of the subtractions and check for matches.

```
def check_card_brand_method1(ctxt):  
    """  
    Check the card brand using method 1.  
  
    Args:  
        ctxt: Encrypted card number context.  
  
    Returns:  
        int: Brand code (0 for Visa, 1 for Master, 3 for Domestic, 4 for NOT valid).  
    """  
    visa_msg = he.feat_msg_generate([4])  
    master_msg = he.feat_msg_generate([5])  
    domestic_msg = he.feat_msg_generate([9])  
  
    visa_ctxt = he.encrypt(visa_msg)  
    master_ctxt = he.encrypt(master_msg)  
    domestic_ctxt = he.encrypt(domestic_msg)  
  
    # Check Visa  
    result_visa = he.subtract(ctxt, visa_ctxt)  
    result_visa = he.equal_zero(result_visa)  
    result_visa_msg = he.decrypt(result_visa)  
  
    # Check Master  
    result_master = he.subtract(ctxt, master_ctxt)  
    result_master = he.equal_zero(result_master)  
    result_master_msg = he.decrypt(result_master)  
  
    # Check Domestic  
    result_domestic = he.subtract(ctxt, domestic_ctxt)  
    result_domestic = he.equal_zero(result_domestic)  
    result_domestic_msg = he.decrypt(result_domestic)  
  
    # Result  
    if round(result_visa_msg[0].real, 2) == 1:  
        msg = 0 # Visa  
    elif round(result_master_msg[0].real, 2) == 1:  
        msg = 1 # Master  
    elif round(result_domestic_msg[0].real, 2) == 1:  
        msg = 3 # Domestic  
    else:  
        msg = 4 # NOT valid  
  
    return msg
```

Implementation - Card Types

Method 2

- Create a binary representation of known card brands (Visa, MasterCard, Domestic).
- Encrypt the binary message.
- Subtract the encrypted binary message from the provided encrypted card number context.
- Decrypt the results of the subtractions and check for matches.

```
def check_card_brand_method2(ctxt):  
    """  
    Check the card brand using method 2.  
  
    Args:  
        ctxt: Encrypted card number context.  
  
    Returns:  
        int: Brand code (0 for Visa, 1 for Master, 3 for Domestic, 4 for NOT valid).  
    """  
    bin = [4] + [0]*15 + [5] + [0]*15 + [9]  
    bin_msg = he.feat_msg_generate(bin)  
    bin_ctxt = he.encrypt(bin_msg)  
  
    # Check Visa  
    result_visa = he.subtract(bin_ctxt, ctxt)  
    result_visa = he.equal_zero(result_visa)  
    result_visa_msg = he.decrypt(result_visa)  
  
    # Check Master  
    bin_ctxt = he.left_rotate(bin_ctxt, 16)  
    result_master = he.subtract(bin_ctxt, ctxt)  
    result_master = he.equal_zero(result_master)  
    result_master_msg = he.decrypt(result_master)  
  
    # Check Domestic  
    bin_ctxt = he.left_rotate(bin_ctxt, 16)  
    result_domestic = he.subtract(bin_ctxt, ctxt)  
    result_domestic = he.equal_zero(result_domestic)  
    result_domestic_msg = he.decrypt(result_domestic)  
  
    # Result  
    if round(result_visa_msg[0].real, 2) == 1:  
        msg = 0 # Visa  
    elif round(result_master_msg[0].real, 2) == 1:  
        msg = 1 # Master  
    elif round(result_domestic_msg[0].real, 2) == 1:  
        msg = 3 # Domestic  
    else:  
        msg = 4 # NOT valid  
  
    return msg
```

Implementation - Card Types

Method 3

- Create a binary representation of known card brands (Visa, MasterCard, Domestic).
- Encrypt the binary message.
- Subtract the encrypted binary message from the provided encrypted card number context.
- Check if the result is equal to zero.
 - If not zero:
 - Left rotate the result by 16 bits and check for MasterCard.
 - If not MasterCard:
 - Left rotate the result by 16 bits again and check for Domestic.
 - If not Domestic, mark as NOT valid.

```
def check_card_brand_method3(ctxt):  
    """  
    Check the card brand using method 3.  
  
    Args:  
        ctxt: Encrypted card number context.  
  
    Returns:  
        int: Brand code (0 for Visa, 1 for Master, 3 for Domestic, 4 for NOT valid).  
    """  
    # Create all bin keys  
    bin = [4] + [0]*15 + [5] + [0]*15 + [9]  
    bin_msg = he.feas_msg_generate(bin)  
    bin_ctxt = he.encrypt(bin_msg)  
  
    # Subtract bin - card_num  
    result = he.subtract(bin_ctxt, ctxt)  
  
    # Check equality to zero for the entire result  
    result = he.equal_zero(result)  
  
    # Check Visa  
    result_visa_msg = he.decrypt(result)  
  
    if round(result_visa_msg[0].real, 2) == 1:  
        msg = 0 # Visa  
    else:  
        # Check Master  
        result_master = he.left_rotate(result, 16)  
        result_master_msg = he.decrypt(result_master)  
  
        if round(result_master_msg[0].real, 2) == 1:  
            msg = 1 # Master  
        else:  
            # Check Domestic  
            result_domestic = he.left_rotate(result_master, 16)  
            result_domestic_msg = he.decrypt(result_domestic)  
  
            if round(result_domestic_msg[0].real, 2) == 1:  
                msg = 3 # Domestic
```

Implementation - Expiry Date

- Get the current date and format it as YYYYMM.
- Encrypt the current date.
- Check if the expiration month is greater than zero.
- Returns:
 - Integer code indicating validity:
 - 1 if valid (expiration month greater than zero).
 - 0 if not valid (expiration month not greater than zero).

```
def check_expiry_date(ctxt, month_ctxt):  
    """  
    Validate the card's expiration date.  
  
    Args:  
        ctxt: Encrypted expiration date context.  
        month_ctxt: Encrypted expiration month context.  
  
    Returns:  
        int: 1 if valid, 0 if not valid.  
    """  
    date = [int(datetime.today().strftime("%Y%m"))]  
    date_ctxt = he.encrypt(date)  
  
    # Check the Month: JAN ~ DEC  
    # Check: month > 0  
    zero_month = he.feat_msg_generate([0])  
    zero_month_ctxt = he.encrypt(zero_month)  
  
    result_month = he.comparing(month_ctxt, zero_month_ctxt)  
    result_month_msg = he.decrypt(result_month)  
  
    if round(result_month_msg[0].real, 2) <= 0.5:  
        msg = 0  
        return msg # NOT
```

Implementation - Card Validity

- Double the value of digits at odd positions.
- If doubling results in a two-digit number, sum the digits.
- Sum all digits of the card number.
- Check if the total sum is divisible by 10.
- Returns:
 - Integer code indicating validity:
 - 1 if valid (total sum divisible by 10).
 - 0 if not valid (total sum not divisible by 10).

```
def validate_card_num(ctxt):  
    """  
    Validate the card number using homomorphic encryption.  
    Args:  
        ctxt: Encrypted card number context.  
    Returns:  
        int: 1 if valid, 0 if not valid.  
    """  
    # Double the value of digits at odd positions  
    double_odd_ctxt = he.multiply(ctxt, 2)  
  
    # If doubling results in a two-digit number, sum the digits  
    cnt, remain = he.division(double_odd_ctxt, 10)  
  
    # Sum the digits of two-digit numbers  
    addition_remain_cnt = he.addition(cnt, remain)  
    addition_remain_cnt_msg = he.decrypt(addition_remain_cnt)  
  
    total = he.feat_msg_generate([0])  
    total_ctxt = he.encrypt(total)  
  
    # Sum all digits  
    for i in range(16):  
        if i % 2 == 0:  
            if round(addition_remain_cnt_msg[i].real, 2) > 0:  
                total_ctxt = he.addition(addition_remain_cnt, total_ctxt)  
            else:  
                total_ctxt = he.addition(double_odd_ctxt, total_ctxt)  
        else:  
            total_ctxt = he.addition(total_ctxt, ctxt)  
  
    addition_remain_cnt = he.left_rotate(addition_remain_cnt, 1)  
    double_odd_ctxt = he.left_rotate(double_odd_ctxt, 1)  
    ctxt = he.left_rotate(ctxt, 1)  
  
    # Check if the total sum is divisible by 10  
    final_cnt, final_remain = he.division(total_ctxt, 10)  
    result = he.equal_zero(final_remain)  
    return result
```

Performance: Method 1 vs. 2 vs. 3

- **Method 3** consistently shows the lowest average processing time across all card brands compared to Method 1 and Method 2.
- Method 2 generally performs better than Method 1 but is slightly slower than Method 3.
- For all card brands, there's a noticeable improvement in efficiency when transitioning from Method 1 to Method 2, and another significant improvement when transitioning from Method 2 to Method 3.
- **Method 3 demonstrates the most efficient performance**, followed by Method 2, and lastly Method 1. This suggests that the optimization strategies implemented in Method 3 significantly enhance the processing efficiency compared to the other two methods.

```

```

Execution - Windows

1. Clone the Repository:

```
git clone https://github.com/jeonghyeonee/Cardify.git
```

2. Setup Virtual Environment:

```
python -m venv your_virtual_environment_name
```

```
your_virtual_environment_name\Scripts\activate
```

```
pip install -r requirements.txt
```

Execution - Linux/MacOS

1. Clone the Repository:

```
git clone https://github.com/jeonghyeonee/Cardify.git
```

2. Setup Virtual Environment:

```
python3 -m venv your_virtual_environment_name
```

```
source your_virtual_environment_name/bin/activate
```

```
pip install -r requirements.txt
```

Execution

1. Run the Web Application:

`python app.py`

2. Access the Web Interface:

Open your web browser and navigate to (<http://localhost:5000>)

3. Input Credit Card Information:

Follow the prompts on the web page to input the credit card number and expiry date in the specified format.

4. View Validation Result:

The program will validate the entered card number and expiry date, determine the card brand, and display the validation result on the web page.

Program Execution

INPUT

- **Valid** card number
- **Valid** Expiration date
- Mastercard

RESULT

Cardify

Card Validation Checking

Input your card number :

5425	2334	3010	9903
------	------	------	------

Card Expiration Date (MM/YY): /

Validation Test Result

Card Number Validity: Valid 😊

Card Brand:  mastercard

Expiration Date Validity : Valid 😊
